April 22, 2018

Abstract. A *biform theory* is a combination of an axiomatic theory and an algorithmic theory that supports the integration of reasoning and computation. These are ideal for specifying and reasoning about algorithms that manipulate mathematical expressions. However, formalizing biform theories is challenging since it requires the means to express statements about the interplay of what these algorithms do and what their actions mean mathematically. This paper describes a project to develop a methodology for expressing and managing mathematical knowledge as a network of biform theories. It is a subproject of MathScheme, a long-term project at McMaster University to produce a framework for integrating formal deduction and symbolic computation.

This paper presents a project named *Biform Theories* that is a subproject of MathScheme [6], a long-term project at McMaster University to produce a framework for integrating formal deduction and symbolic computation. The motivation, background ideas, objectives, work plan status, and related work for the project are described in the sections below.

1 Motivation

Jacques should complete this section with help from Yasmine with examples.

2 Background Ideas

A *transformer* is an algorithm that implements a function $\mathcal{E}^n \rightarrow \mathcal{E}$ where \mathcal{E} is a set of expressions. Transformers can manipulate expressions in various ways. Simple transformers, for example, build bigger expressions from pieces, select components of expressions, or check whether a given expression satisfies some syntactic property. More sophisticated transformers manipulate expressions in mathematically meaningful ways. We call these kinds of transformers *syntax-based mathematical algorithms (SBMAs)* [11]. Examples include algorithms that

^{*} This research was supported by NSERC.

apply arithmetic operations to numerals, factor polynomials, transpose matrices, and symbolically differentiate expressions with variables. The *computational behavior* of a transformer is the relationship between its input and output expressions. When the transformer is an SBMA, its *mathematical meaning* is the relationship between the mathematical meanings of its input and output expressions.

A *biform theory* T is a triple (L, Π, Γ) where L is a language of some underlying logic, Π is a set of transformers that implement functions on expressions of L , and Γ is a set of formulas of L [3,9,16]. L includes, for each transformer $\pi \in \Pi$, a name for the function implemented by π . The members of Γ are the *axioms* of T . They specify the meaning of the nonlogical symbols in L including the names of the transformers of T . In particular, Γ may contain specifications of the computational behavior of the transformers in Π and of the mathematical meaning of the SBMA's in Π . We say T is an *axiomatic theory* if Π is empty and an *algorithmic theory* if Γ is empty.

Formalizing a biform theory in the underlying logic requires an infrastructure for reasoning about the expressions manipulated by the transformers as syntactic entities. The infrastructure provides a basis for *metareasoning with reflection* [12]. There are two main approaches for obtaining this infrastructure [11]. The *local approach* is to produce a deep embedding of a sublanguage L' of L that include all the expressions manipulated by the transformers of Π . The *global approach* is to replace the underlying logic of L with a logic such as [12] that has an inductive type of *syntactic values* that represent the expressions in L and global quotation and evaluation operators.

A complex body of mathematical knowledge can be represented in accordance with the *little theories method* [15] as a *theory graph* [20] consisting of axiomatic theories as nodes and theory morphisms as directed edges. A *theory morphism* is a meaning-preserving mapping from the formulas of one axiomatic theory to the formulas of another. The theories — may have different underlying logics — serve as abstract mathematical models and the morphisms serve as information conduits that enable theory components such as definitions and theorems to be transported from one theory to another [2]. A theory graph enables mathematical knowledge to be formalized in the most convenient underlying logic at the most convenient level of abstraction using the most convenient vocabulary. The connections made by the theory morphisms in a theory graph then provide the means to find this knowledge and apply it in other contexts.

A *biform theory graph* is a theory graph whose nodes are biform theories. Having the same benefits as theory graphs of axiomatic theories, biform theory graphs are well suited for representing mathematical knowledge that is expressed both axiomatically and algorithmically.

3 Project Objectives

The general objective of the Biform Theories project is:

GenObj. Develop a methodology for expressing and managing mathematical knowledge as a biform theory graph.

Our strategy for achieving this general objective is to pursue the following specific objectives:

SpecObj 1. Design a logic **Log** that is version of simple type theory [10] with an inductive type of syntactic values, a global quotation operator, and a global evaluation operator. In addition to a syntax and semantics, define a proof system for **Log** and a notion of a theory morphism from one axiomatic theory of **Log** to another. Demonstrate that SBMAs can be defined in **Log** and that their mathematical meanings can be stated and proved in using **Log**'s proof system.

SpecObj 2. Produce an implementation **Impl** of **Log**. Demonstrate that SBMAs can be defined in **Impl** and that their mathematical meanings can be stated and proved in **Impl**.

SpecObj 3. Enable biform theories to be defined in **Impl**. Introduce a mechanism for applying transformers defined outside of **Impl** to expressions of **Log**.

SpecObj 4. Enable theory graphs of biform theories to be defined in **Impl**. Introduce mechanisms for transporting definitions, theorems, and transformers from a biform theory T to an instance T' of T via a theory morphism from T to T' .

SpecObj 5. Design and implement in **Impl** a scheme for defining generic transformers in a theory graph T that can be specialized, when transported to an instance T' of T , using the properties exhibited in T' .

4 Work Plan Status

The work plan for the project is to achieve the five specific objectives described above more or less in the order of their presentation. This section describes the parts of the work plan that have been completed as well as the parts that remain to be done.

SpecObj 1: Logic with Quotation and Evaluation

This objective has been largely been achieved. We have developed CTT_{qe} [14], a version of Church's type theory [7] with global quotation and evaluation operators. (Church's type theory is a popular form of simple type theory with lambda notation.) The syntax of CTT_{qe} has the machinery of \mathcal{Q}_0 [1], Andrews' version of Church's type theory plus an inductive type ϵ of syntactic values, a partial quotation operator, and a typed evaluation operator. The semantics of CTT_{qe} is based on Henkin-style general models [19]. The proof system for CTT_{qe} is an extension of the proof system for \mathcal{Q}_0 .

We show in [14] that CTT_{qe} is suitable for defining SBMAs and stating and proving their mathematical meanings. In particular, we prove within the proof system for CTT_{qe} the mathematical meaning of an symbolic differentiation algorithm for polynomials.

We have also defined CTT_{uqe} [13], a variant of CTT_{qe} in which undefinedness is incorporated in CTT_{qe} according to the traditional approach to undefinedness [8]. Better suited than CTT_{qe} as a logic for interconnecting axiomatic theories, we have defined in CTT_{uqe} a notion of a theory morphism [13].

SpecObj 2: Implementation of the Logic

We have produced an implementation of CTT_{qe} called HOL Light QE [5] by modifying HOL Light [18], a simple implementation of the HOL proof assistant [17]. HOL Light QE provides a built-in global infrastructure for metareasoning with reflection. Over the next couple years we plan to test this infrastructure by formalizing a variety of SBMAs in HOL Light QE.

SpecObj 3: Biform Theories

No work on this objective has been done, but we expect it will be a straightforward task to implement biform theories and the application of external transformer in HOL Light QE.

SpecObj 4: Biform Theory Graphs

We proposed in [4] a biform theory graph test case consisting of eight biform theories encoding natural number arithmetic. We produced partial formalizations of this test case [4] in CTT_{uqe} [13] using the global approach for metareasoning with reflection and in Agda [22,23] using the local approach. After we have finished with SpecObj 2 and SpecObj 3, we intend to formalize this test case in HOL Light QE.

SpecObj 5: Specializable Transformers

Jacques should complete this subsection. Please reference Pouya's thesis [21].

5 Related Work

Jacques should complete this section, referring as necessary to the related work section in [14].
